Please contact them if you need access. This page describes the API (Application Programming Interface) for the library IBH, which is used to control the presented electronic device and its integrated hardware. IBH4Step7 Server Interfaces All interfaces are based on the STEP7 messaging standard. All components and libraries are based on the STEP7 API. The interconnects are shown in the following figure. Additional interfaces for an automatic testing of the components are shown in this figure. The diagram shows the overview of the main server interfaces of IBH. Depending on the source of the data, different interconnections are used. The configuration of the interconnections is shown in the next figure. The following figure shows the table structure of the source data in each case. To connect the interface, a remote control object must be defined. The interface definition is shown in the following figure: For the control of the class of the object, the remote control object must be set (Default is 'STEP7RemoteControl'). The reason is that the working of the server is controlled by the remote control object. After the initialization, a reference to the control server can be used for the sending and receiving of the messages. The remote control object can be defined in a different way than the 'STEP7RemoteControl' type, for example the path name of a script file. The configuration of the control server for the following API is shown in the next figure. Below, the same steps are executed for the WBS7 interface, which serves as the master interconnect of the digital interface for the STEP7 communication. The interface definition is shown in the following figure. 82157476af
